

HTML, MEET CSS

CSS Basics

- CSS stands for "Cascading Style Sheets", and was invented by Hakon Lie.
- It allows web designers to add style to HTML. It's a unifying standard for rendering text, color, and images across browsers and devices.
- You can use CSS to create responsive designs and to improve usability and localization.

Why "Cascading?"

- CSS is stored in a sheet listing various style rules.
- These rules are **cascading**, which means they're implemented in a logical, hierarchical manner.
 - Style sheets are read top to bottom, and rules that come farther down supersede rules that appeared closer to the top.
 - Rules can be prioritized for different screen sizes.
 - Backup rules can also be created in case some styles may not work.

Using CSS

CSS is written in **declarations**. A CSS declaration has two parts:

- **Property**: the aspect you wish to style (for example: text-weight or color)
- **Value**: the exact style you wish to apply (for example: bold or red)

When writing a CSS declaration:

- Define the **selector**, the HTML element should be styled by the CSS.
- Set **parameters** by adding curly braces around the styles you want to apply.
- Include the style you want to apply.

When adding CSS, make sure to include punctuation, line breaks, and indentation so that your code can be read and properly implemented.

To give multiple elements the same style, include them both as selectors, separated by a comma.

```
h1, p {  
  text-align: center;  
  color: red;  
}
```

There are two ways to add CSS to a site.

****Internal CSS:**** CSS that's within the HTML file, indicated by a ``<style>`` tag.

****External CSS:**** A separate CSS file that's linked to your site, also known as an external style sheet.
